and M

Vol. 14, No. 25

Week Ending

U.S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE

PUBLIC HEALTH SERVICE

DIPHTHERIA

No cases of diphtheria were reported in the United States during the week ended June 26, this being the fourth occasion in a period of 6 weeks that no cases have been reported. The cumulative totals of cases through the 25th week of 1965 and the previous 4 years are shown in the table at right. An analysis of the numbers of cases reported and their origin during 1965 shows that of the 80 cases in the United States, 67 or 83.8 percent have originated in 4 census regions. In these census regions, the States of Texas and Alabama had 15 and 11 cases respectively; there were 8 cases in Georgia, 7 each in Minnesota and South Dakota, and 6 in Florida.

SALMONELLA SURVEILLANCE - Summary for April

During April a total of 1,274 isolations of salmonellae from human sources were reported to the Salmonella Surveillance Unit for an average weekly total of 318. This represented a slight increase of 15 recoveries per week over March 1965 and a decrease of 57 isolations per week over April 1964. The trend observed in the first quarter

of 1965 is continuing with total isolations running approximately 2 percent fewer than the human recoveries during the same period last year.

The seven most commonly reported serotypes from human sources during April were:

| RANK | SEROTYPE | NUMBER | PERCENT | RANK LAST MONTH |

EPIDEMIOLOGICAL NOTES SALMONELLA GASTROENTERITIS - Washington, D.C. area

A large outbreak of gastroenteritis due to Salmonella meleagridis is currently under investigation in the metropolitan area of Washington, D.C. Over 350 cases have been reported with onsets of illness between May 11 and June 8. Cases are known to have occurred in the District of Columbia, Maryland, New Jersey, and Virginia. Incubation periods ranged from 12 to 36 hours. The illnesses have been mild, only three persons requiring hospitalization; there have been no deaths. The symptomatology has been that of moderately severe diarrhea, abdominal cramps and low grade fever; bloody diarrhea was not a part of the clinical picture. Among ill persons, S. meleagridis has been recovered from stool cultures in over 30 instances.

Investigations to date indicate that the common source in this outbreak was in a large restaurant—delicatessen in Washington, D.C., employing 116 persons, and offering restaurant facilities on the premises, retail sale of food and home catering services. All cases reported to date had consumed food either in the restaurant, or sold retail, or served at private parties catered by the delicatessen. Attack rates of about 50 percent have been documented among persons attending the catered parties.

Salmonella meleagridis has been recovered from a

wide variety of foodstuffs originating in this catering center. These include coleslaw, sliced salami, corned beef, roast beef, turkey, and "pigs-in-a-blanket". To date, 45 of the persons employed as food handlers have been identified as excreters of S. meleagridis, only one of whom has admitted to clinical illness. Extensive environmental cultures have been obtained within the establishment, two of these yielding S. meleagridis from one of 5 meat slicers and from a food grinder, respectively.

The premises were closed for 2 weeks and an extensive revision of the physical plant was instituted. All employees are being required to have two successive rectal swabs negative for salmonella before returning to work. Investigations are continuing.

(Reported by Dr. Murray Grant, Director of Public Health and his colleagues in the District of Columbia Department of Public Health; Dr. John H. Janney, Acting Chief, Division of Epidemiology and his colleagues in the Maryland Department of Health; Dr. J.D. Kenley, Director of the Bureau of Epidemiology, Virginia State Department of Health; Dr. Ralph Beachley, Director, Arlington County Health Department, and a team from the Communicable Disease Center, Atlanta, Georgia.)

STAPHYLOCOCCAL FOOD POISONING - Petersburg, Virginia

An outbreak of gastroenteritis caused by hemolytic *Staphylococcus aureus*, phage type 54/6/7/47/81, has been reported by the Virginia State Department of Health. Twelve persons are known to have become ill following the consumption of ham sandwiches.

By midnight on the date of onset the twelve cases had been reported by physicians and by the local hospital in patients who ranged in age from 19 to 47 years. Symptoms included nausea, vomiting, abdominal pain and slight diarrhea without fever; three patients showed signs of shock and six were hospitalized. Rectal swabs and stool specimens were obtained from hospitalized patients at 1:30 a.m. All affected had consumed ham sandwiches with mayonnaise at a local sandwich shop. The incubation period was estimated to be between 2 and 4 hours.

The owner of the sandwich shop was called at his home around midnight, and an inspection of the shop was made. Samples of food eaten by those affected were collected. The restaurant was noted to be in good condition with excellent refrigeration. All items of sanitation met the requirements of state and local regulations. The food handlers were examined and throat, nasal and rectal swabs were taken; an infected burn on the finger of one individual was noted, and a swab was taken for culture. This individual had cooked and prepared the ham, starting about 6:00 a.m. on the day of the outbreak. The ham was ready for serving at noon; it was sliced and

served from a steam table (temperature of about $140^{\circ}F$). Eighty ham sandwiches were prepared and served. Only those who consumed ham after 2:00 p.m. became ill, and it was noted that the illness was more severe amongst those eating as late as 4:00-5:00 p.m.

All specimens were taken to the Virginia State Health Department Laboratory for culture. The mayonnaise showed no growth. The ham which had been removed from the steam table at 2:00 p.m. to cool, grew coagulase positive, S. aureus, phage type 54/6/7/47/81. Cultures were negative for other pathogens, i.e., streptococcal fecalis, clostridium perfringens, salmonella and shigella.

In excess of a billion organisms per gram of ham were recovered. Rectal and stool specimens from four of the six patients, and the swab taken from the food handler's burn grew the same strain of staphylococcus. Other cultures from patients and food handlers were negative for pathogens.

Prompt reporting by the hospital and physicians, the immediate action by the health department, and the cooperation of the sandwich shop owner prevented the development of any subsequent cases.

(Reported by Dr. J.B. Kenley, Director, Bureau of Epidemiology, Virginia State Department of Health, investigated by Mr. Stanley R. Hutcherson, Chief Sanitarian and Dr. C.J. Stuart, Health Officer, Petersburg.)

POLIOMYFLITIS

Arizona

Two cases of paralytic poliomyelitis have occurred recently in Yuma County, Arizona and both cases were in unimmunized preschool age children. Type I poliovirus was isolated from stool specimens submitted on both cases which are listed below:

| | Age | Sex | Onset | | Disease Status | Vace IPV | oine OPV |
|----|----------|--------|--------|---|-------------------|-------------|-------------|
| 1. | 8 months | Female | May 18 | I | Paralytic | 0 | 0 |
| 2. | 4 years | Male | May 26 | I | Paralytic | 0 | 0 |

Yuma County (population 47,000) conducted a mass oral poliomyelitis vaccination program in 1962, when more than 90 percent of the populace received Type I poliovirus vaccine. On Sunday, June 27, last, a vaccination program utilizing Type I poliovirus vaccine from the Communicable Disease Center epidemic reserve was conducted in Yuma County, with emphasis on the preschool and school age groups. More than 30,000 doses of vaccine were administered in the one day.

(Reported by Dr. Philip M. Hotchkiss, State Epidemiologist, Arizona State Department of Health and a team from the Communicable Disease Center, Atlanta, Georgia.)
